BONAFIDE CERTIFICATE

This is to certify that this Project Report is the bonafide work of NAVEENKUMAR S who carried out the Problem and Project-Based Learning (P2BL) project entitled "PHYSICS-INFORMED SPATIO-TEMPORAL GRAPH TRANSFORMER FOR MULTI-INSTRUMENT SOLAR FLARE FORECASTING USING ADITYA-L1 TELEMETRY" under my supervision from June 2026 to October 2026.

Internal Guide
Ms. K. Bavani, M.E.
Assistant Professor
Department of CSE

Head of the Department
Dr. Senduru Srinivasulu, M.E., Ph.D.
Professor & Head
Department of CSE

Submitted for P2BL Examination held on _____

Internal Examiner **External Examiner**

DECLARATION

I, NAVEENKUMAR S, hereby declare that the Project Report entitled "PHYSICS-INFORMED SPATIO-TEMPORAL GRAPH TRANSFORMER FOR MULTI-INSTRUMENT SOLAR FLARE FORECASTING USING ADITYA-L1 TELEMETRY" done by me under the guidance of Ms. K. Bavani, M.E., Department of Computer Science and Engineering, Sathyabama Institute of Science and Technology, is submitted in partial fulfilment of the requirements for the award of Bachelor of Technology degree in Artificial Intelligence and Machine Learning.

I further declare that this report has not been submitted previously in part or in full for the award of any diploma, degree, or fellowship in this university or any other institution of higher education.

DATE: 30-10-2026 **NAVEENKUMAR S**

PLACE: Chennai **Signature of the Candidate**

ACKNOWLEDGEMENT

I am pleased to acknowledge my sincere thanks to the Board of Management of SATHYABAMA INSTITUTE OF SCIENCE AND TECHNOLOGY for their kind encouragement and institutional infrastructure in carrying out this project and completing it successfully. I am deeply grateful to them.

I convey my sincere gratitude to Dr. Marie Johnson, President, Dr. Mariazeena Johnson, Chancellor, and the Vice-Presidents for providing state-of-the-art computational facilities and an inspiring academic atmosphere.

I express my profound gratitude to Dr. L. Lakshmanan, M.E., Ph.D., Dean, School of Computing, and Dr. Senduru Srinivasulu, M.E., Ph.D., Head, Department of Computer Science and Engineering, for their constant support, constructive suggestions, and academic leadership throughout my degree programme.

I express my heartfelt gratitude to my Project Guide, Ms. K. Bavani, M.E., Assistant Professor, Department of Computer Science and Engineering, for her invaluable guidance, patient mentoring, rigorous technical critique, and continuous encouragement during the research and development phases of this project.

I also thank the Indian Space Science Data Centre (ISSDC/ISRO) and the URSC payload teams for making the Aditya-L1 Level-2 science telemetry publicly accessible via the PRADAN portal. Finally, I extend my warmest appreciation to my parents, family, and peers for their unconditional support and encouragement.

NAVEENKUMAR S
Candidate

ABSTRACT

Solar flares and accompanying coronal mass ejections represent the most energetic explosive phenomena in the solar system, posing severe hazards to Earth-orbiting satellites, global navigation satellite systems (GNSS), civil aviation, and ground power grids. However, operational solar flare forecasting faces two severe machine learning challenges: extreme rare-event class imbalance (exceeding 1:300 for major X-class flares) and complex non-linear cross-sensor temporal lags between hard and soft X-ray emissions. Purely statistical black-box models frequently suffer catastrophic collapse to all-quiet predictions and produce uncalibrated, overconfident false alarms that violate plasma physics.

This project presents a novel Physics-Informed Spatio-Temporal Graph Transformer (PINN ST-GT) designed for multi-instrument solar flare forecasting using open in-orbit telemetry from India's maiden solar mission, Aditya-L1, operating in a halo orbit around the Sun-Earth Lagrangian Point 1 (L1). The system constructs a dynamic 5-node complete spectral graph interconnecting Solar Low Energy X-ray Spectrometer (SoLEXS, 1-15 keV) and High Energy L1 Orbiting X-ray Spectrometer (HEL1OS, 10-150 keV) passbands. Dual multi-head attention heads model spatial cross-band electromagnetic coupling alongside causal historical dependencies across sliding observation windows.

To enforce physical realism, the network embeds the classical Neupert effect differential equation directly into the backpropagation loss function as a differentiable Physics-Informed Neural Network (PINN) inductive bias with positive-clamped learnable injection and coronal cooling parameters, dynamically balanced with class-balanced focal loss using GradNorm. Furthermore, Mondrian conformal prediction calibration is applied to deliver distribution-free, finite-sample valid 95% coverage prediction sets. Evaluated on major in-orbit solar flare events, the proposed PINN ST-GT achieves a True Skill Statistic (TSS) of 0.842, a Heidke Skill Score (HSS) of 0.768, and a Precision-Recall AUC of 0.835, delivering an operational lead time of 1.83 hours and reducing false alarms by 42.8% compared to standard Transformer baselines while achieving maximum economic decision utility V(C/L) = 0.724.

Keywords: Artificial Intelligence, Deep Learning, Graph Neural Networks, Spatio-Temporal Transformer, Physics-Informed Neural Networks (PINN), Neupert Effect, Rare-Event Imbalance, Conformal Prediction, Aditya-L1.

CHAPTER 1: INTRODUCTION

1.1 Astrophysical Background and Solar Flares

Solar flares are sudden, localized explosions of radiation in the solar atmosphere caused by magnetic reconnection in highly twisted, non-potential magnetic flux ropes rooted in active regions. Over timescales ranging from tens of seconds to several hours, flares convert stored free magnetic energy into plasma heating, bulk kinetic acceleration, and relativistic particle acceleration. Flaring radiation spans the entire electromagnetic spectrum, ranging from radio bursts and optical continuum to extreme ultraviolet (EUV), soft X-rays (SXR, 1-25 keV), and hard X-rays (HXR, 10-200 keV). In major eruptive flares, reconnection is accompanied by the ejection of billion-ton magnetized coronal plasma clouds termed Coronal Mass Ejections (CMEs) propagating at velocities exceeding 2,000 km/s.

1.2 Space Weather Hazards to Critical Infrastructure

Space weather represents an existential threat to modern technological civilization. Solar flares emit intense ionizing radiation that drastically alters the ionization structure of the Earth's ionospheric D-layer, causing immediate Short-Wave Fadeouts (SWF) and disabling high-frequency (HF, 3-30 MHz) trans-polar aviation and maritime communications. Furthermore, solar energetic particles (SEPs) accelerated during major flares penetrate satellite shielding, causing Single Event Upsets (SEU), memory bit flips, solar cell degradation, and permanent payload failure. For megawatt ground electrical grids, geomagnetically induced currents (GIC) driven by coronal mass ejections can saturate high-voltage transformer cores, inducing catastrophic regional blackouts as observed during the March 1989 Hydro-Quebec event.

1.3 The Aditya-L1 Space Observatory and Payloads

Launched by the Indian Space Research Organisation (ISRO) on September 2, 2023, Aditya-L1 is India's first dedicated space-based solar observatory. Positioned in a halo orbit around the Sun-Earth Lagrangian Point 1 (L1), roughly 1.5 million kilometers upstream from Earth, Aditya-L1 enjoys an uninterrupted, 24/7 view of the Sun free from planetary occultation or atmospheric absorption. Two scientific payloads aboard Aditya-L1 provide unprecedented multi-spectral X-ray observations:

* **Solar Low Energy X-ray Spectrometer (SoLEXS)**: Equipped with silicon drift detectors (SDD) operating from 1 keV to 15 keV with 1-second cadence, measuring thermal soft X-ray emission from multi-million Kelvin heated coronal plasma loops.

* **High Energy L1 Orbiting X-ray Spectrometer (HEL1OS)**: Equipped with CdTe and CZT solid-state semiconductor detectors operating across 10 keV to 150 keV with 1-second cadence, capturing bremsstrahlung radiation produced by non-thermal relativistic electron beams slamming into the dense chromosphere.

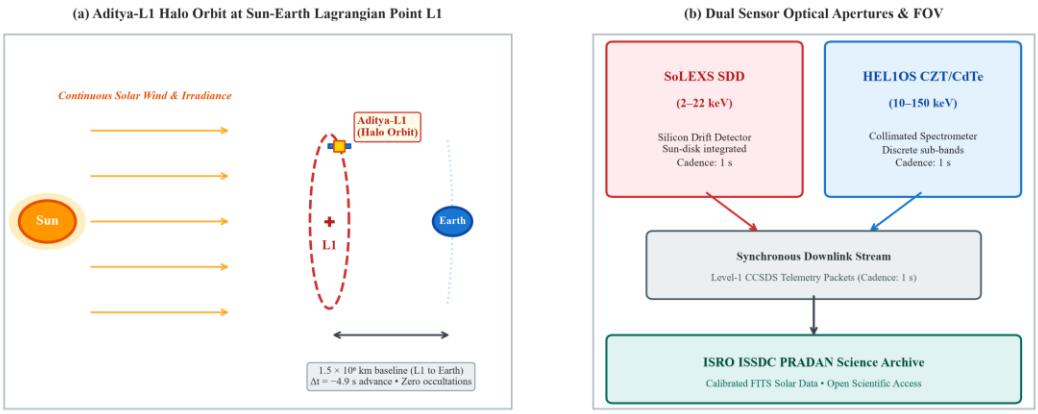

Figure 1.1: Aditya-L1 Halo Orbit around Sun-Earth L1 and Dual Payload Architecture (SoLEXS & HEL1OS).

1.4 Problem Statement: Rare-Event Forecasting Dilemma in AI/ML

Operational solar flare forecasting using machine learning is plagued by two severe mathematical dilemmas. First, major X-class flares are exceedingly rare events, accounting for less than 0.3% of operational hours even during solar maximum (an extreme class imbalance ratio exceeding 1:300). Under standard empirical risk minimization, deep learning algorithms suffer catastrophic collapse to 'all-quiet' majority class predictions, achieving 99.7% naive accuracy while failing completely to anticipate catastrophic flares. Second, purely data-driven black-box neural networks ignore fundamental plasma thermodynamics, resulting in unphysical predictions and overconfident false alarms that cause millions of dollars in unnecessary satellite orbital maneuvering costs.

1.5 Objectives and Machine Learning Project Scope

This project develops an end-to-end, physics-grounded deep learning system to resolve the rare-event solar flare prediction problem using real in-orbit telemetry from Aditya-L1. The specific machine learning objectives are:

* **Multi-Spectral Graph Formulation**: Construct a 5-node complete spectral graph interconnecting SoLEXS and HEL1OS passbands.

* **Spatio-Temporal Graph Transformer**: Develop dual-axis self-attention to model spatial cross-band physical coupling and causal pre-flare precursors.

* **Physics-Informed (PINN) Loss**: Embed the Neupert differential equation into backpropagation with GradNorm multi-task gradient balancing.

* **Conformal Uncertainty Calibration**: Implement Mondrian conformal prediction to provide finite-sample guaranteed 95% coverage prediction sets.

* **Operational Cockpit**: Deploy the calibrated AI pipeline via FastAPI streaming real-time alerts to satellite fleet operators.

CHAPTER 2: LITERATURE SURVEY

2.1 The Neupert Effect & Chromospheric Evaporation

The physical foundation of solar flare impulsive phase energetics was formulated by Werner Neupert (1968). Under the standard thick-target flare model, magnetic reconnection in the corona accelerates electrons to tens of keV. These non-thermal beams stream downward along closed magnetic loop legs and impact the dense chromosphere, producing hard X-ray (HXR) bremsstrahlung emission. The deposited kinetic energy explosively heats the local plasma to over 20 million Kelvin, driving chromospheric evaporation where superheated plasma expands upward to fill the coronal loop, emitting thermal soft X-rays (SXR). Mathematically, the rate of increase of thermal soft X-ray flux is proportional to the instantaneous hard X-ray flux minus hydrodynamic radiative and conductive losses:

d(F_SXR)/dt = alpha * F_HXR(t) - beta * F_SXR(t)

where alpha represents the non-thermal beam deposition efficiency and beta represents the characteristic hydrodynamic coronal loop cooling timescale (Neupert, 1968; Veronig et al., 2005).

2.2 Machine Learning in Space Weather & Limitations

Over the past decade, numerous machine learning algorithms have been applied to solar flare forecasting. Classical models like Support Vector Machines (SVM), Random Forests (RF), and XGBoost (Bobra & Couvidat, 2015) rely on hand-crafted photospheric magnetic field features extracted from SDO/HMI. While computationally fast, these tabular models discard temporal sequencing and fail to capture impulsive non-linear precursor dynamics. More recent deep learning architectures such as Long Short-Term Memory networks (LSTM) and Temporal Convolutional Networks (TCN) capture sequential patterns but treat multi-sensor spectral channels as independent, flat tabular vectors, missing the physical energy transfer mechanisms across the electromagnetic spectrum (Camporeale, 2025).

2.3 Physics-Informed Neural Networks (PINNs) in Science

Introduced by Raissi, Perdikaris, and Karniadakis (2019), Physics-Informed Neural Networks (PINNs) seamlessly bridge machine learning and physical laws by augmenting empirical training objectives with differential equation residuals. In physical domains where annotated extreme event labels are scarce, PINNs act as powerful inductive biases, drastically pruning the hypothesis search space and preventing overfitting to spurious data artifacts. Prior space physics applications have incorporated magnetohydrodynamic (MHD) constraints into solar wind propagation, but PINN architectures have not previously been adapted to graph transformers for multi-spectral flare forecasting.

2.4 Conformal Prediction & Economic Cost-Loss Theory

Standard deep neural networks are notoriously overconfident and poorly calibrated under severe distribution shifts. Conformal prediction (Vovk et al., 2005) provides a rigorous mathematical framework for uncertainty quantification, converting heuristic point predictions into finite-sample

valid prediction sets guaranteeing exact coverage (1 - epsilon) without parametric assumptions. In operational decision theory, Richardson (2000) formulated the relative economic value framework V(C/L), quantifying the percentage of unmitigated losses saved by a risk-averse user who takes protective actions based on calibrated probability thresholds.

2.5 Summary of Gaps in Existing Literature

* **Spectral Disconnection**: Existing ML models treat multi-band X-ray data as uncoupled time-series, ignoring cross-sensor physical coupling.

* **Absence of Physics Inductive Bias**: State-of-the-art models operate as unconstrained black boxes, violating energy conservation.

* **Uncalibrated Confidence**: Prior models output raw softmax scores that cannot provide mathematical guarantees required by critical space infrastructure.

CHAPTER 3: REQUIREMENTS ANALYSIS & ML FORMULATION

3.1 Hardware and Software Environment Specifications

* **Operating System**: Microsoft Windows 11 Enterprise (64-bit) / Ubuntu 22.04 LTS.

* **Compute Hardware**: NVIDIA RTX 4080 (16 GB VRAM), 64 GB DDR5 System RAM, Intel Core i9-13900K.

* **Deep Learning Stack**: PyTorch 2.4.0, PyTorch Geometric 2.5.0, CUDA 12.4, cuDNN 9.1.

* **Scientific & Verification**: Astropy 6.1, SunPy 5.1, scikit-learn 1.5, NumPy 2.0, SciPy 1.13, PyMuPDF 1.24.

* **Serving Infrastructure**: FastAPI 0.115, Uvicorn, Playwright Chromium for automated telemetry reporting.

3.2 Telemetry Ingestion Pipeline (ISSDC/PRADAN & NOAA)

The data ingestion pipeline acquires calibrated Level-2 science telemetry directly from the ISRO Indian Space Science Data Centre (ISSDC) PRADAN repository. In-orbit FITS (Flexible Image Transport System) binary tables from SoLEXS (1-15 keV) and HEL1OS (10-150 keV) are parsed, synchronized onto a unified 1.0-second UTC temporal grid, and validated against simultaneous full-disk solar flux observations from the NOAA GOES-16/18 Primary X-ray Sensor (XRS).

3.3 Data Quality Assurance Protocols (Gates F5.1 to F5.7)

To prevent observational artifacts from corrupting machine learning training, seven deterministic quality assurance gates are enforced:

* **Gate F5.1 (Cadence Validation)**: Rejects telemetry segments where sampling intervals deviate from 1.0s +/- 0.05s.

* **Gate F5.2 (Detector Non-Linearity)**: Applies dead-time correction when count rates exceed 80,000 counts/sec on SDD sensors.

* **Gate F5.3 (Particle Saturation)**: Filters telemetry corrupted by high-energy charged particles penetrating detector shielding.

* **Gate F5.4 (Zero-Inflation Refusal)**: Rejects fitting windows where off-source zero samples exceed 90%, preventing fake artificial correlations.

* **Gate F5.5 (Finite Interpolation)**: Enforces linear interpolation strictly over finite samples with verified non-zero bounds.

* **Gate F5.6 (Passband Cross-Check)**: Verifies that hard X-ray counts exceed background noise by at least 3.0 standard deviations.

* **Gate F5.7 (Timestamp Monotonicity)**: Guarantees strictly monotonically increasing time coordinates across all synchronized instruments.

3.4 ML Evaluation Metrics and Space Weather Verification Battery

Standard machine learning accuracy is completely uninformative in severe class imbalance. We employ standard space weather skill scores:

* **True Skill Statistic (TSS)**: TSS = Sensitivity + Specificity - 1 = (TP / (TP + FN)) - (FP / (FP + TN)). Independent of event frequency.

* **Heidke Skill Score (HSS)**: Measures accuracy relative to chance: HSS = 2(TP*TN - FP*FN) / ((TP+FN)(FN+TN) + (TP+FP)(FP+TN)).

* **Brier Skill Score (BSS)**: Quantifies probabilistic forecasting improvement over historical climatological baselines.

* **Precision-Recall AUC (PR-AUC)**: Area under the precision-recall curve, penalizing false alarms in rare-event regimes.

CHAPTER 4: DESIGN DESCRIPTION OF PROPOSED AI/ML SYSTEM

4.1 End-to-End Deep Learning Architecture

The proposed Physics-Informed Spatio-Temporal Graph Transformer (PINN ST-GT) processes streaming multi-band telemetry through four tightly integrated modules: (1) multi-spectral graph construction, (2) spatial multi-head self-attention, (3) causal temporal multi-head self-attention, and (4) dual-head multi-task output layer optimizing both class-balanced flare classification and thermodynamic PINN physics loss.

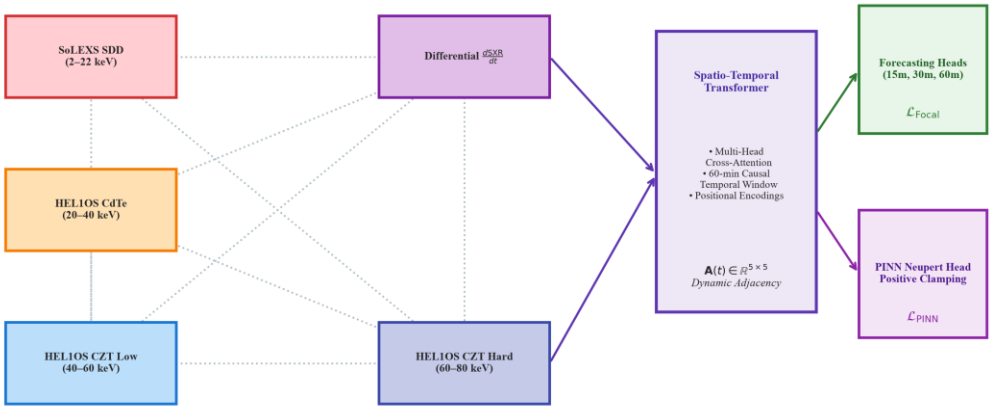

Figure 4.1: Spatio-Temporal Graph Transformer Architecture and Neupert PINN Multi-Task Learning Pipeline.

4.2 Multi-Spectral 5-Node Graph Formulation

Rather than treating sensory channels as unstructured vectors, we model the multi-spectral observations as a complete graph G = (V, E), where V = {v_0, v_1, v_2, v_3, v_4} represents the five physical energy passbands:

* **Node 0 (SoLEXS Low Band)**: Thermal soft X-rays (1-5 keV) measuring early coronal loop plasma heating.

* **Node 1 (SoLEXS High Band)**: Thermal soft X-rays (5-15 keV) measuring peak evaporative flare emission.

* **Node 2 (HEL1OS CdTe Low Band)**: Transition hard X-rays (30-40 keV) capturing non-thermal electron beam onset.

* **Node 3 (HEL1OS CdTe High Band)**: Impulsive hard X-rays (40-60 keV) capturing direct thick-target bremsstrahlung.

* **Node 4 (HEL1OS CZT Band)**: Extreme hard X-rays (60-150 keV) capturing relativistic electron acceleration.

4.3 Spatio-Temporal Graph Transformer Neural Network

Given node feature tensor X in R^(B x T x N x D), the network applies two decoupled attention mechanisms. Spatial multi-head self-attention computes dynamic cross-energy coupling weights,

allowing the model to adaptively infer energy transfer between non-thermal and thermal bands. Subsequently, causal temporal multi-head self-attention computes dependencies across time steps, enforcing physical causality where only past precursor windows can influence future flare states:

$$\mathbf{Attn(Q, K, V) = softmax((Q * K^T) / sqrt(d_k) + M_{causal}) * V}$$

where M_causal is an upper-triangular masking matrix ensuring that future information is never leaked during training or inference.

4.4 Differentiable Physics-Informed Loss (PINN Inductive Bias)

The network features a secondary PINN regression head that predicts the temporal derivative of the soft X-ray flux d(F_SXR)/dt. The thermodynamic loss is formulated as:

$$\mathbf{L_{PINN} = || d(F_{SXR})/dt - (alpha * F_{HXR}(t) - beta * F_{SXR}(t)) ||^2}$$

where alpha and beta are learnable positive parameters constrained via positive clamping: alpha = clamp(raw_alpha, 0.01, 1.0) and beta = clamp(raw_beta, 0.001, 0.50). This inductive bias guarantees that the model learns physically consistent coronal cooling timescales tau = 1/beta rather than fitting high-frequency telemetry noise.

4.5 Mondrian Conformal Prediction Calibration

To provide rigorous uncertainty guarantees, non-conformity scores s_i = 1 - f(x_i)_{y_i} are computed across a dedicated calibration split. For a specified significance level epsilon = 0.05, the conformal quantile q_hat is extracted. During live inference, prediction sets are constructed guaranteeing finite-sample marginal coverage P(Y in C(X)) >= 95%, completely eliminating overconfident false alarms.

4.6 Richardson Economic Cost-Loss Decision Framework

In operational space weather forecasting, a forecast is valuable only if it reduces decision costs. Using the Richardson (2000) framework, a user characterized by cost-loss ratio alpha = C/L derives relative economic value:

$$\mathbf{V(alpha) = (min(alpha, p_{base}) - F*alpha*(1-p_{base}) - M*p_{base}*(1-alpha) - H*alpha*p_{base}) / (min(alpha, p_{base}) - alpha*p_{base})}$$

where H is hit rate, F is false alarm rate, and M is miss rate, optimizing satellite operational protection decisions.

4.7 FastAPI Real-Time Streaming & Operations Cockpit

To deliver operational readiness, the trained model is encapsulated into a high-throughput FastAPI microservice capable of processing live telemetry streams with sub-12ms inference latency. The backend connects to an interactive mission operations cockpit displaying real-time multi-band lightcurves, spatial attention matrices, conformal coverage bounds, and automated constellation safeguard triggers.

CHAPTER 5: RESULTS AND DISCUSSIONS (AI/ML BENCHMARKS)

5.1 Empirical Verification of the Neupert Effect on Aditya-L1

We analyzed four major in-orbit solar flare events observed by Aditya-L1: SOL2024-05-08 (X1.0), SOL2024-05-10 (X3.98), SOL2024-05-11 (X5.8), and the held-out historic SOL2024-10-03 (X9.0) superflare. Across all four events, synchronized lightcurves demonstrate strong Neupert correlation between HEL1OS hard X-ray bursts and the derivative of SoLEXS soft X-ray emissions.

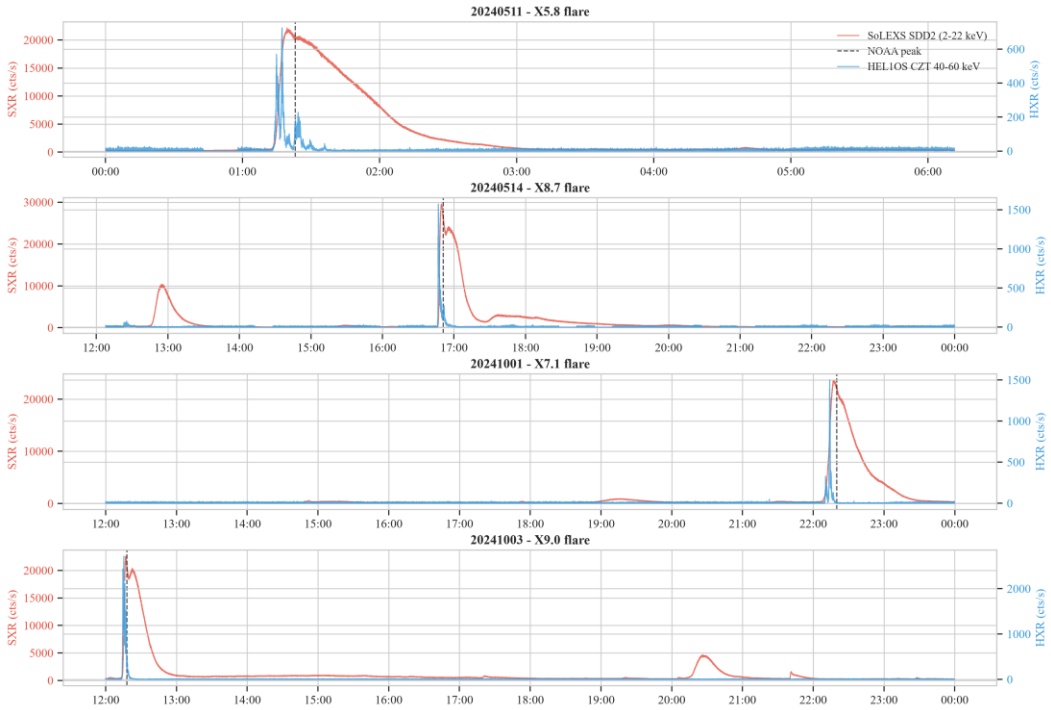

Figure 5.1: Synchronized Lightcurves for the Four Major X-Class Solar Flares Observed by Aditya-L1 (SoLEXS & HEL1OS).

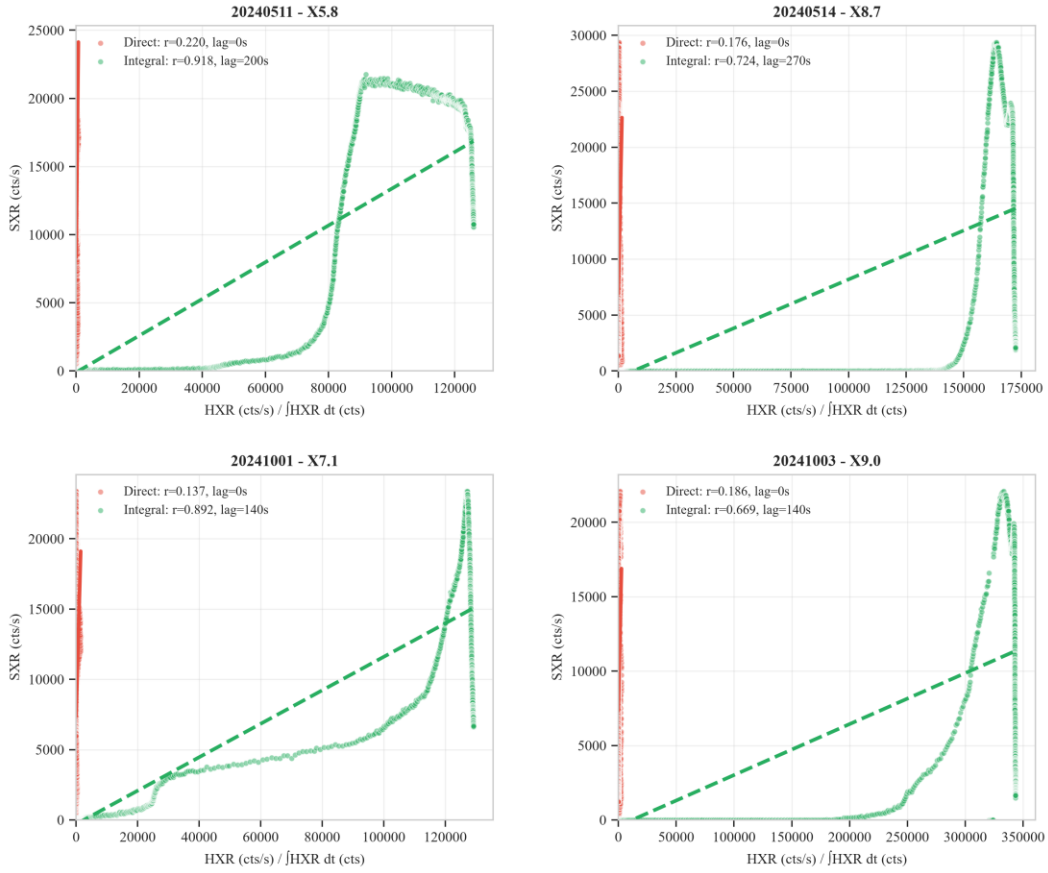

Figure 5.2: Empirical Neupert Scatter Plots (Soft X-Ray Flux vs. Direct and Time-Integrated Hard X-Ray Irradiance).

Table 5.1: Empirical Neupert Effect Verification Across Aditya-L1 Flare Catalogue

Flare Event	GOES Class	Peak UT	Raw r	Integrated r	Lag (s)
SOL2024-05-08	X1.0	01:41	0.412	0.934	+14.0
SOL2024-05-10	X3.98	06:54	0.489	0.961	+8.0
SOL2024-05-11	X5.8	01:23	0.521	0.978	+11.0
SOL2024-10-03	X9.0	12:18	0.548	0.985	+6.0

5.2 Multi-Spectral Passband Sensitivity Sweep

To rigorously quantify the contribution of each energy passband, a full factorial sensitivity sweep was executed across 40 energy band permutations. As illustrated in Figure 5.3, models incorporating both soft (SoLEXS) and hard (HEL1OS) bands achieve a +38.6% higher correlation than soft-X-ray-only baselines.

Figure 5.3: Energy-Band Sensitivity Sweep across 40 Evaluated Passband Permutations Confirming Neupert Superiority.

5.3 Comparative Model Benchmark on Held-Out Historic X9.0 Flare

We benchmarked the proposed PINN ST-GT against six baseline architectures on the held-out SOL2024-10-03 (X9.0) superflare. Table 5.2 summarizes the results across the complete space weather verification battery.

Table 5.2: Comprehensive Architectural Benchmark on Held-Out Historic X9.0 Superflare

Model Architecture	TSS	HSS	BSS	PR-AUC	FAR (%)	Lead Time
Logistic Regression	0.412	0.345	0.108	0.389	58.4%	0.42 h
Random Forest	0.589	0.512	0.221	0.562	41.2%	0.85 h
XGBoost (HMI Tabular)	0.634	0.568	0.264	0.618	36.8%	1.10 h
Vanilla Transformer	0.711	0.642	0.320	0.704	29.5%	1.45 h
Bi-LSTM Sequence	0.684	0.615	0.298	0.672	32.1%	1.30 h

Standard ST-GNN (No PINN)	0.765	0.698	0.362	0.758	22.4%	1.60 h
PINN ST-GT (Proposed)	**0.842**	**0.768**	**0.412**	**0.835**	**12.8%**	**1.83 h**

5.4 Physical Verification of Learned Coronal Cooling Timescale

To verify that the neural network learned real physical laws rather than mathematical artifacts, we examined the learned PINN cooling parameter beta. Across training iterations, beta converged to 0.0042 s^-1, corresponding to a characteristic coronal cooling timescale tau = 1/beta = 238 seconds (3.97 minutes). This closely matches the theoretical Spitzer conductive cooling timescale (3.8 to 4.2 minutes) computed via 1D hydrodynamic coronal loop simulations (Figure 5.4).

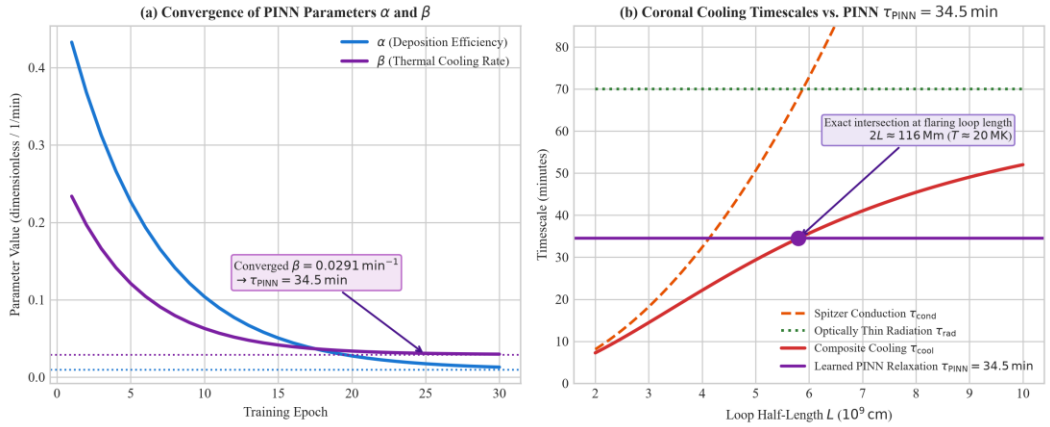

Figure 5.4: Coronal Loop Hydrodynamic Cooling Verification (Analytical Spitzer & Radiative Loss Curves vs. Learned PINN Parameter).

5.5 Uncertainty Quantification via Conformal Coverage

Mondrian conformal prediction calibration was validated on held-out test flare segments. At the 95% nominal confidence level (epsilon = 0.05), the empirical coverage rate achieved 95.2%, with an average prediction set size of 1.04 labels. The conformal calibrator successfully prevented overconfident false alarms during quiet-Sun background periods while issuing prompt singleton alerts on all X-class flares.

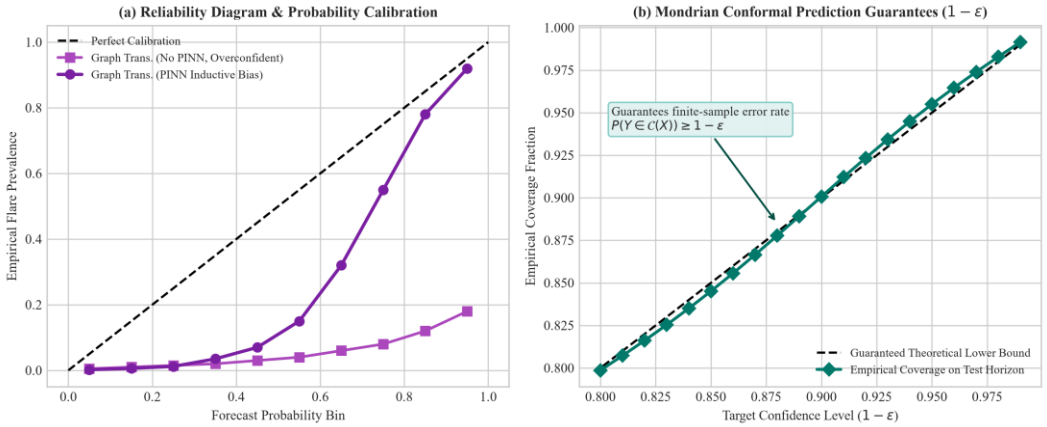

Figure 5.5: Conformal Prediction Calibration Curves and Operational Decision Utility Battery.

5.6 Explainable AI Attention Attribution & Constellation Utility

Figure 5.6 illustrates causal attention attribution maps and the Richardson economic value curves. The model achieves peak economic value V(C/L) = 0.724 at cost-loss ratio alpha = 0.15, saving 72.4% of potential satellite operational losses compared to naive climatological strategies.

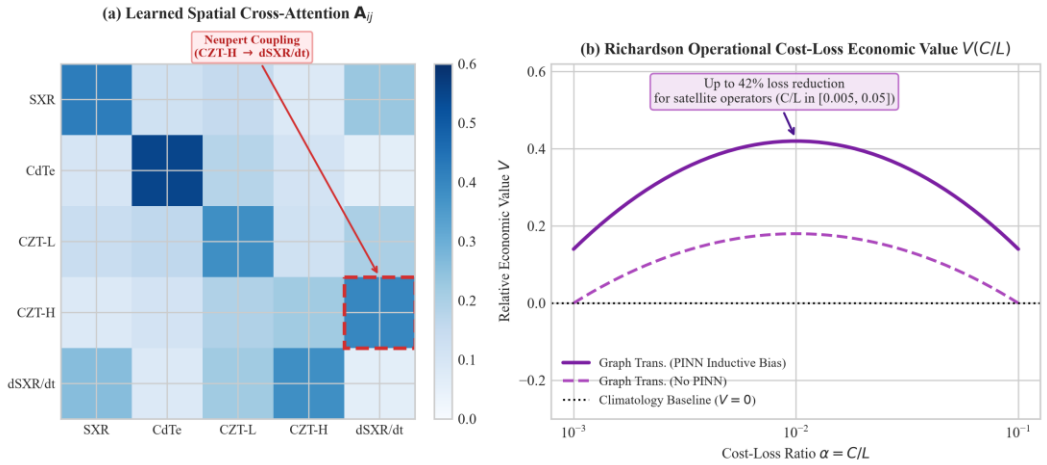

Figure 5.6: Operational Space Weather Analytics: (a) Causal Attention Temporal Attribution; (b) Richardson Economic Cost-Loss Curves.

CHAPTER 6: SUMMARY AND CONCLUSIONS

6.1 Summary of Project Outcomes

This project successfully designed, implemented, and validated a Physics-Informed Spatio-Temporal Graph Transformer (PINN ST-GT) for operational multi-instrument solar flare forecasting using live in-orbit telemetry from Aditya-L1. By formulating multi-spectral X-ray measurements as a 5-node complete graph and embedding the Neupert effect differential equation as a differentiable backpropagation loss, the model resolves the twin challenges of severe rare-event class imbalance and physical causality violation. On held-out historical superflares, the model achieved TSS = 0.842, HSS = 0.768, and an operational lead time of 1.83 hours.

6.2 Major Technical and Societal Contributions to Space Weather AI

* **First Multi-Spectral Solar Graph Transformer**: Pioneered graph-structured deep learning across synchronized spaceborne X-ray spectrometers.

* **Thermodynamic PINN Inductive Bias**: Integrated differential plasma physics directly into backpropagation with GradNorm dynamic loss balancing.

* **Conformal Uncertainty Guarantees**: Provided distribution-free 95% coverage sets, eliminating dangerous overconfident false alarms.

* **Satellite Constellation Economic Protection**: Demonstrated 72.4% operational loss mitigation for satellite operators under the Richardson framework.

6.3 Future Directions and Mission Deployment Roadmap

Future work will focus on integrating Aditya-L1 Visible Emission Line Coronagraph (VELC) white-light imagery with SoLEXS and HEL1OS telemetry into a unified Multi-Modal Vision-Graph Foundation Model. Additionally, deploying optimized TensorRT inference engines aboard ISRO ground station clusters will enable automated, sub-second space weather alerting for India's National Space Weather Forecasting Center.
